

Technical Interview - Senior / Lead Engineer

BRIEF

At Linkz, we are looking for a Senior Engineer who can elevate our platform's quality, reliability, scalability, and security standards as the business continues to grow. The ideal candidate should have 6 to 10 good engineering years managing public-facing production systems.

This role goes beyond software development. We are seeking someone with strong engineering judgment who can make thoughtful trade-offs between speed, risk, technical debt, operational stability, and business priorities. As our platform scales, there will be constant decisions around what to prioritize immediately, what to improve incrementally, and where pragmatic compromises are acceptable with clear understanding of their impact.

Candidate is encouraged to incorporate the above understanding and apply it with sound engineering judgment in the following use cases, demonstrating the ability to balance business priorities, technical quality, operational reliability, security risks, delivery timelines, and long-term platform sustainability.

ASSESSMENT

This assessment is designed to evaluate engineering judgment, system design thinking, software quality, operational awareness, security considerations, and the ability to make thoughtful trade-offs in a real-world scenario.

You are encouraged to use AI-assisted development tools during this assessment. However, the evaluation will focus heavily on your technical decisions, architecture, operational thinking, handling of edge cases, and your ability to explain trade-offs and compromises.

The objective is not to build a perfect production system, but to demonstrate how you think as a senior engineer when designing and implementing a business-critical workflow.

SCENARIO

Build a small public seat reservation platform using any TypeScript stack with the following requirements.

The application should display 3 available seats that can be reserved by authenticated users.

Users should be able to:

- Login with session expiry at 90 days
- Select a seat
- Proceed to payment
- Successfully reserve the seat upon payment completion

Candidates should demonstrate practical engineering approaches that reflect common real-world scenarios, including thoughtful handling of trade-offs, operational concerns, failure cases, and system reliability.

You are free to choose your preferred:

- Framework
- Database
- Infrastructure approach
- Authentication provider
- Mock payment provider
- Deployment method

SUBMISSION

Please submit your assessment as a GitHub repository containing:

- Source code
- README documentation
- Setup instructions
- Environment configuration guidance
- Any supporting scripts or documentation required to run the project locally

If the repository is private, please provide access to the reviewers.

Typically, this system is expected to be completed within approximately 2 hours of focused implementation time. The assessment is designed to evaluate engineering judgment and technical decision-making rather than feature completeness or production polish.

END
